# Checkers Solved

Schaeffer et al. 2007

Artificial Intelligence for Games 25.04.2019 Fabian Jäger

#### Overview

25.04.2019

#### History

- 1950 start with Arthur Samuel's pioneering work in machine learning
- 1963 first win of a checker program
- 1989 start of the search for a champion challenging program
- 1992 peak, over 200 processors were devoted simultaneously
- 1994 defeat of a world champion (Chinook), but not solved yet

Definition Of Solving

## 3 States of Solving:

- 1.ultra weakly: Outcome known for starting position
- 2.weakly: Outcome and Strategy known for the starting position
- 3.strong: Outcome and Strategy known for the every position

# Checkers

# Rules:

- Kings can move one field, but backwards, too
- 8x8 field, but only on black played
- 2 types of figures
  => 5\*(10^20) positions
- Restriction:
  - Forced-Capture

# Solving Methods

#### Perfect play from both players

25.04.2019

**Checkers Solved** 

# Solving Methods

# 3 Components:

- 1. Database
- 2. Proof-tree manager
- 3. Proof-tree solver
  - 1.Alpha-Beta
  - 2.Depth first proof number (Df-Pn)

Number of Positions (logarithmic)

#### Database

	Pieces	Number of positions
•1989-1996 8 piece	1	120
In 2001 only 1 month for 8 niece	2	6,972
	3	261,224
•2001-2005 10 pieces	4	7,092,774
	5	148,688,232
	6	2,503,611,964
	7	34,779,531,480
$\Gamma_{0} = \frac{1}{2} \left( \frac{1}{2} - \frac{1}{2} \right) \left( \frac{1}{2} - \frac{1}{2} - \frac{1}{2} - \frac{1}{2} \right) \left( \frac{1}{2} - \frac{1}{2} - \frac{1}{2} - \frac{1}{2} \right) \left( \frac{1}{2} - \frac{1}{2} - \frac{1}{2} - \frac{1}{2} \right) \left( \frac{1}{2} - \frac{1}{2} -$	8	406,309,208,481
FOR T PIECE: $(32+28) = 120$	9	4,048,627,642,976
	10	34,778,882,769,216
	Total 1—10	39,271,258,813,439

# forced-capture => fast reduction to 10 => much smaller game tree

25.04.2019

#### Proof-tree manager

Maintains a tree of the proof in progress Identifies positions which are interested

1. Several hundred at a time Proof number Search

- 1. Disprove value := minimum number of leaf nodes needed for disproof
- 2. Prove value := minimum number of leaf nodes needed for the proof

### Proof number

#### Alpha-Beta-Pruning

#### Thresholds for pruning trees

- 1. Alpha := lower threshold
- 2. Beta := upper threshold
- 3. initialized with +/- "infinity"

 $b^d => b^d/(d/2)$ 

### Depth-First Proofing Number

- •Similar to Alpha-Beta
- Creates threshold for disproof/proof number
- follows best children until a proof is found

=> if no proof is found a heuristics value is calculated (Chinook)

#### Iteration

- Most iterate on search depthManager uses threshold t:
  - scores ≤-t are losses
  - scores  $\geq$ t are wins
  - increase t

#### Results

#### Only 19 starting positions have to be considered: 1. 300 three-move openings, more than 100 are duplicates 2.rest can be proven to be irrelevant by an alpha-beta search

25.04.2019

### Results

- •search effort: 10^14 (with only alpha beta 10^24)
- 10 pieces database is 237 Gb large (154 positions per byte)
- •50 computers simultaneously for search tree for 3 years

# Conclusion

Correctness:

- many potential sources of errors (algorithm bugs, data transmission errors)
- computations have been independently verified
- outcome manually checked
- Chance of error propagation is small
